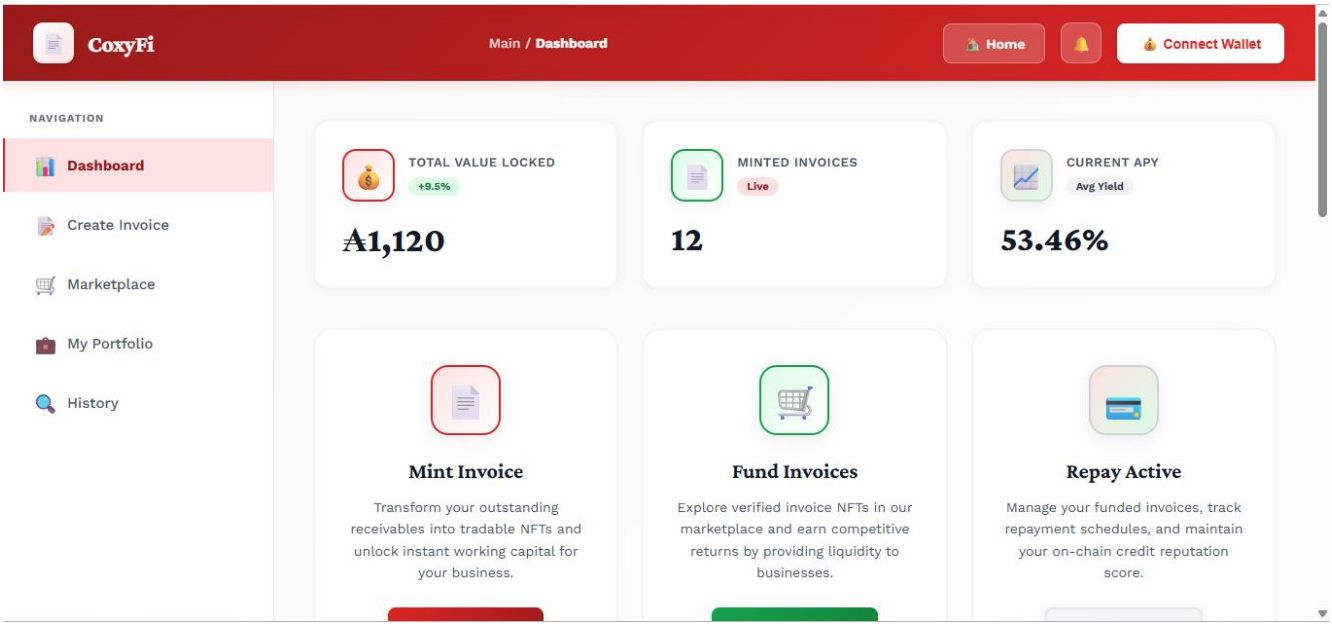
16. Summary

## 1. Introduction

The Invoice Finance DApp front end is designed to let issuers create tokenized invoices, allow investors to review and fund those invoices, and support issuer repayment and transaction review from a single connected experience.

The interface follows a professional financial dashboard pattern: a clean header, focused action cards, clear transaction feedback, and structured data views that make blockchain actions understandable to non-technical users.



## 2. Design Goals and Principles

- Make blockchain actions feel familiar by using standard dashboard and form patterns.
- Keep critical actions visible: connect wallet, create invoice, fund invoice, repay invoice, review history.
- Present trust signals clearly through status messages, wallet identity, and document verification links.
- Reduce user error with labeled inputs, strong visual hierarchy, and transaction feedback.
- Keep the experience readable on both desktop and smaller laptop screens.

## 3. Front-End Information Architecture

The front end is organized around the following major user-visible areas:

- Public / landing orientation
- Wallet connection and session establishment
- Invoice creation form
- Available invoice marketplace
- Issuer-funded invoice repayment area
- Recent transaction activity
- Transaction history lookup and CSV export
- Status and modal feedback layers

## 4. Global Layout and Navigation

Across major screens, the layout should stay consistent so users do not lose context while moving between tasks.

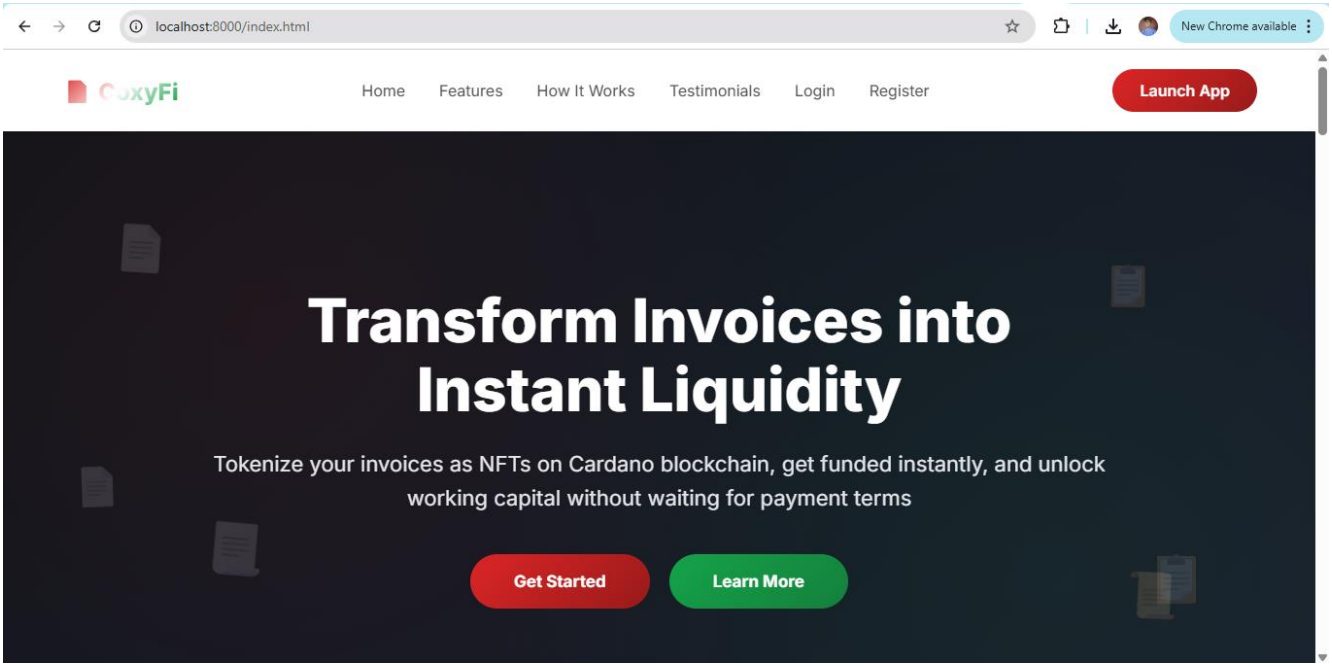
- Top header with product identity and wallet connection control
- Primary content area divided into cards or content sections
- Action-first layout with forms and invoice lists above secondary analytics
- Footer or status area for confirmations, warnings, and errors
- Consistent button language across the product

## 5. Public Entry Experience

### 5.1 Landing / Home Screen

The landing experience should introduce the product clearly: what invoice finance is, who it serves, and the primary actions available after connection. It should emphasize trust, simplicity, and fast onboarding.

- Headline describing invoice tokenization / financing value proposition
- Short explanation of issuer and investor use cases
- Primary CTA to connect wallet or sign in
- Optional feature summary cards
- Optional statistics or trust indicators

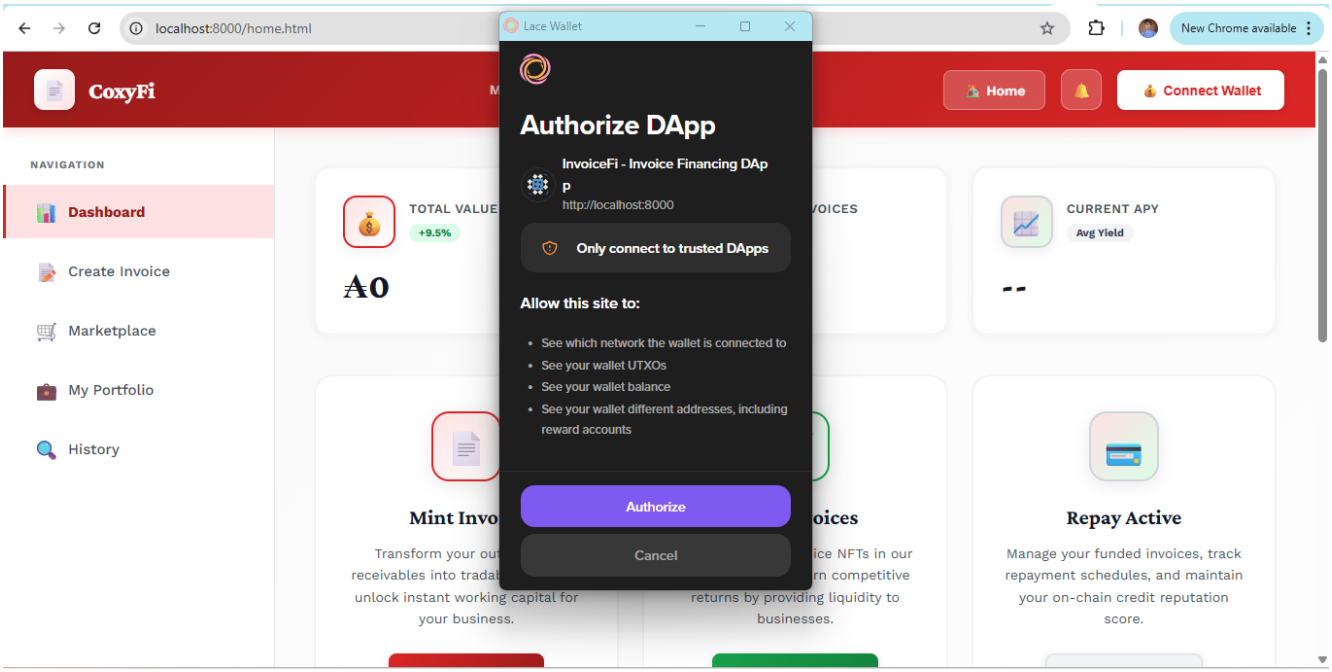


### 5.2 Wallet Connection and Account Access

Wallet connection is the entry gate into the operational dApp. The design should clearly explain when a user is connected, what wallet was connected, and whether the wallet is recognized for the current account.

- Connect Wallet button in the header

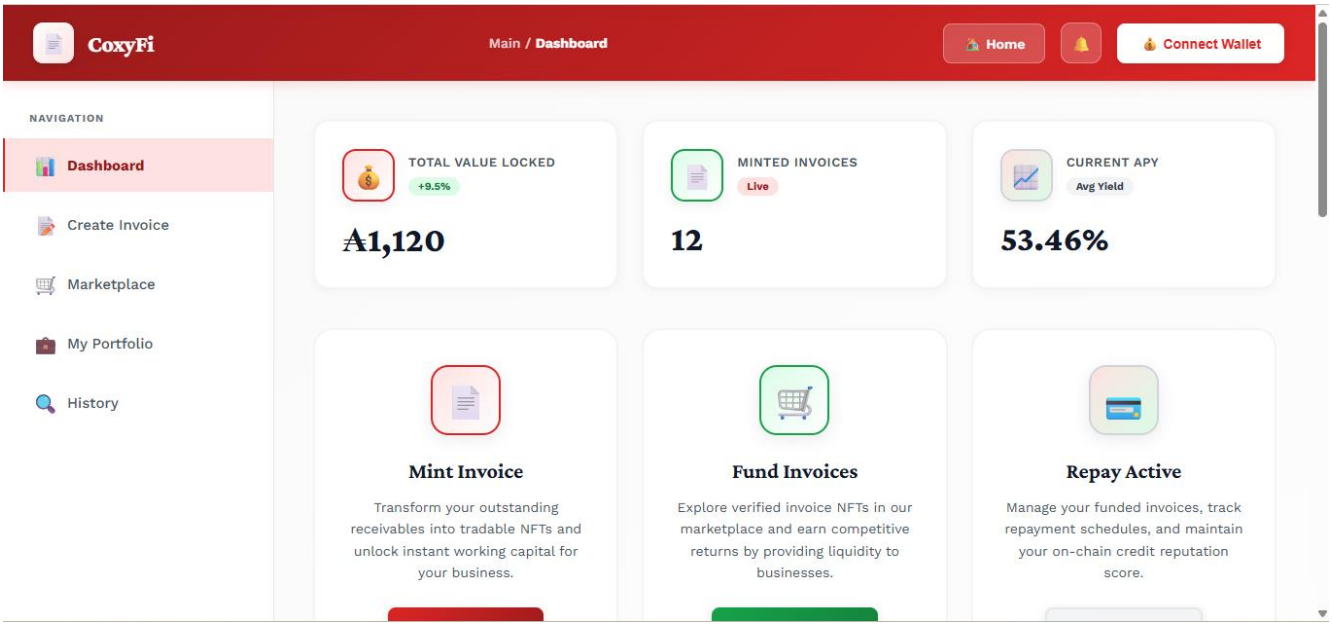
- Wallet prompt feedback and loading state
- Wrong-wallet warning modal
- Successful wallet binding or verification message



## 6. Dashboard Overview

The dashboard is the operational center of the product. It should present active tasks first and keep informational widgets secondary.

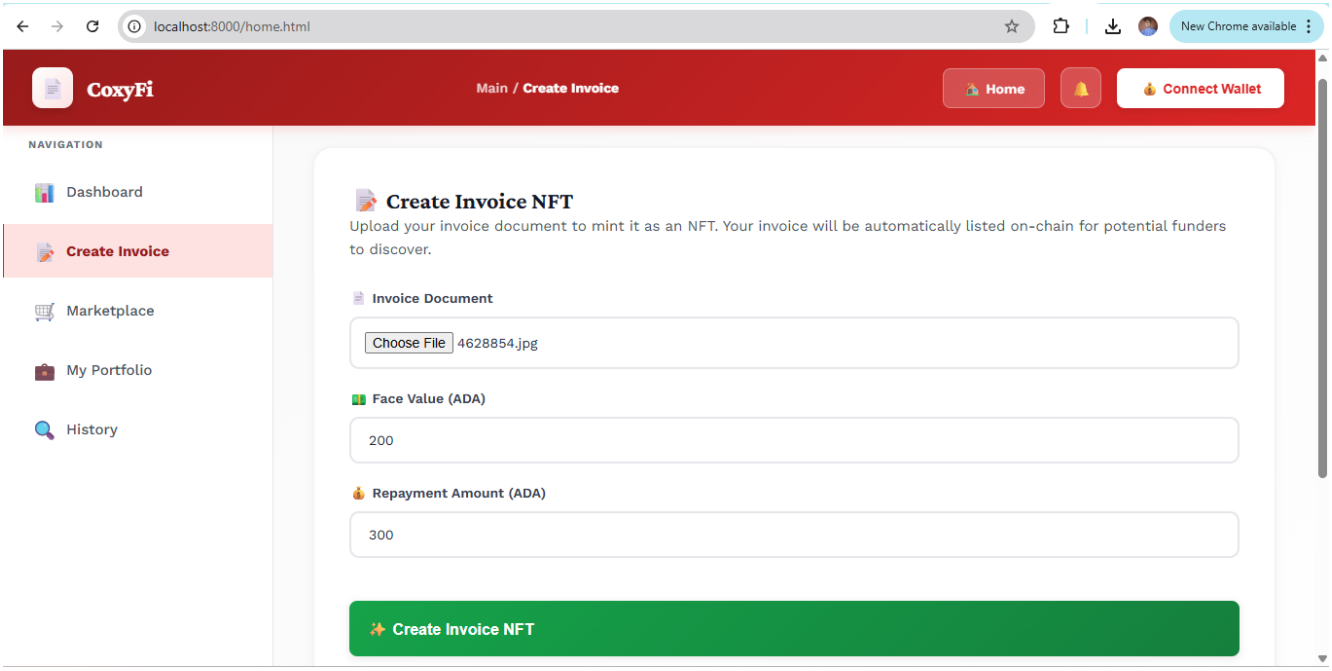
- Create Invoice card placed prominently for issuers
- Available Invoices marketplace block for investors
- Issuer-funded invoices section for repayment tasks
- Live stats cards for platform activity
- Recent transaction table for quick monitoring



## 7. Create Invoice Experience

The create invoice screen or card should support a straightforward three-part flow: document upload, economic values, and mint/submit confirmation.

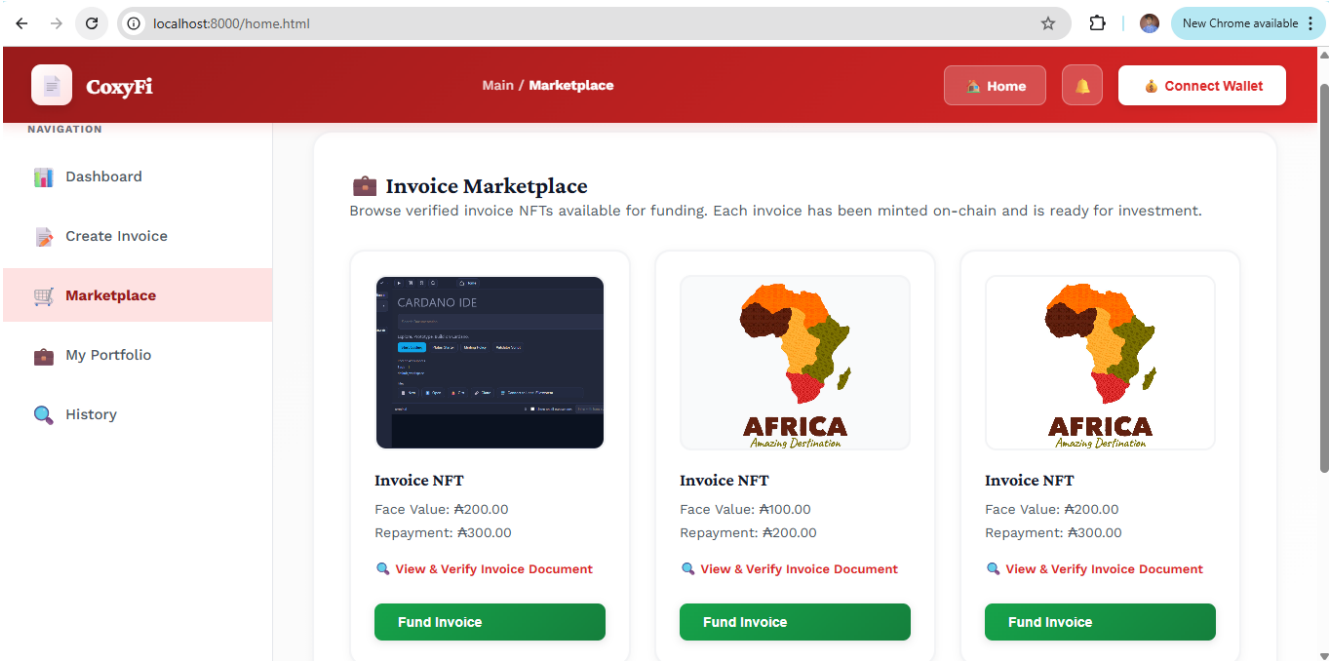
- File upload input with accepted invoice document format guidance
- Face value field
- Repayment amount field
- Primary Create Invoice button
- Validation messages for missing file or invalid amounts
- Post-submit success state with transaction hash and verification link



## 8. Invoice Marketplace / Funding View

The funding view is where investors browse available invoice opportunities. Each invoice card should allow quick comprehension without opening secondary views first.

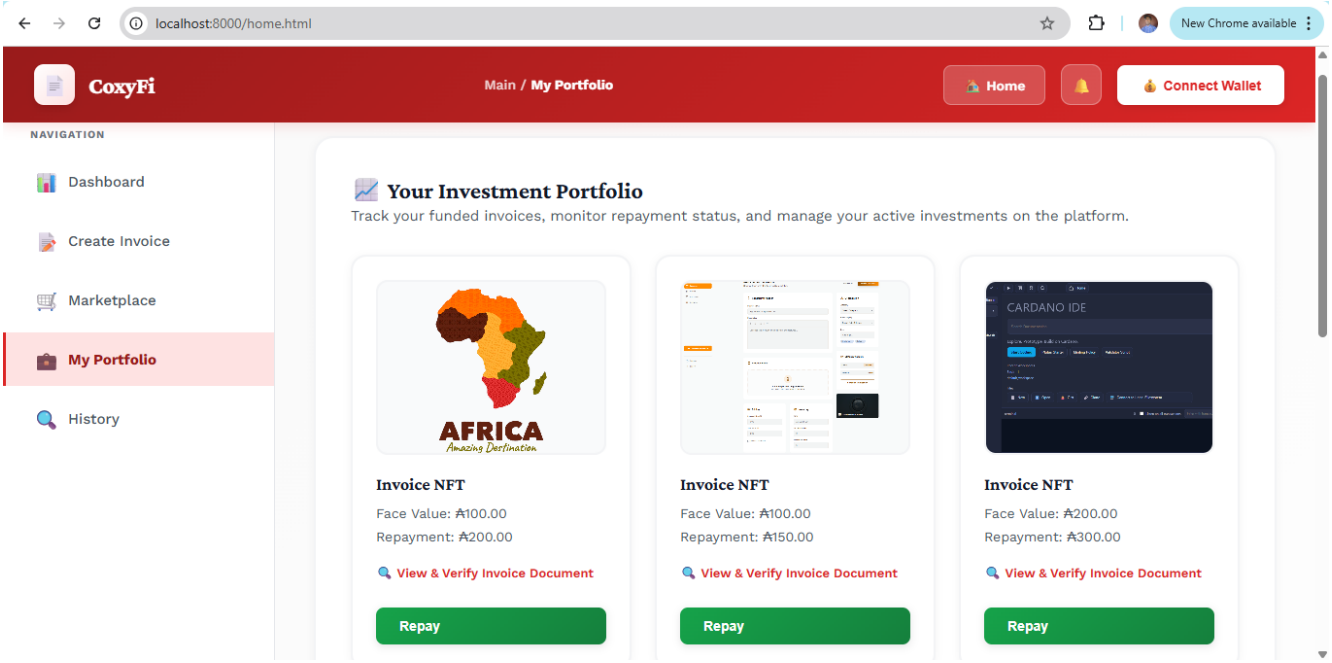
- Invoice preview image or document preview
- Face value display
- Repayment amount display
- Document verification / open link
- Fund Invoice action button
- Empty-state design when no invoice is available



## 9. Funded Invoice / Repayment View

The repayment view is tailored for issuers. It should only show invoices belonging to the connected issuer and only those that are in a repayable state.

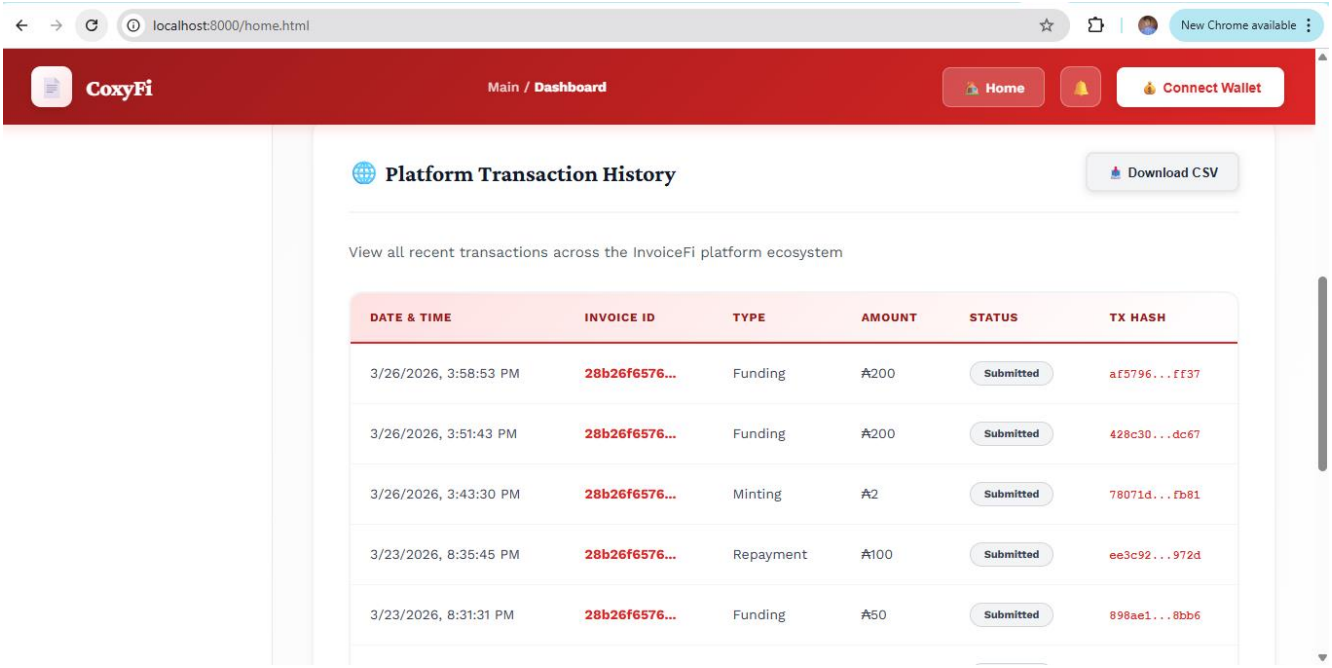
- Repayable invoice cards clearly separated from available invoices
- Repayment amount emphasis
- Repay button with confirmation step
- Post-repayment success state and closed lifecycle feedback

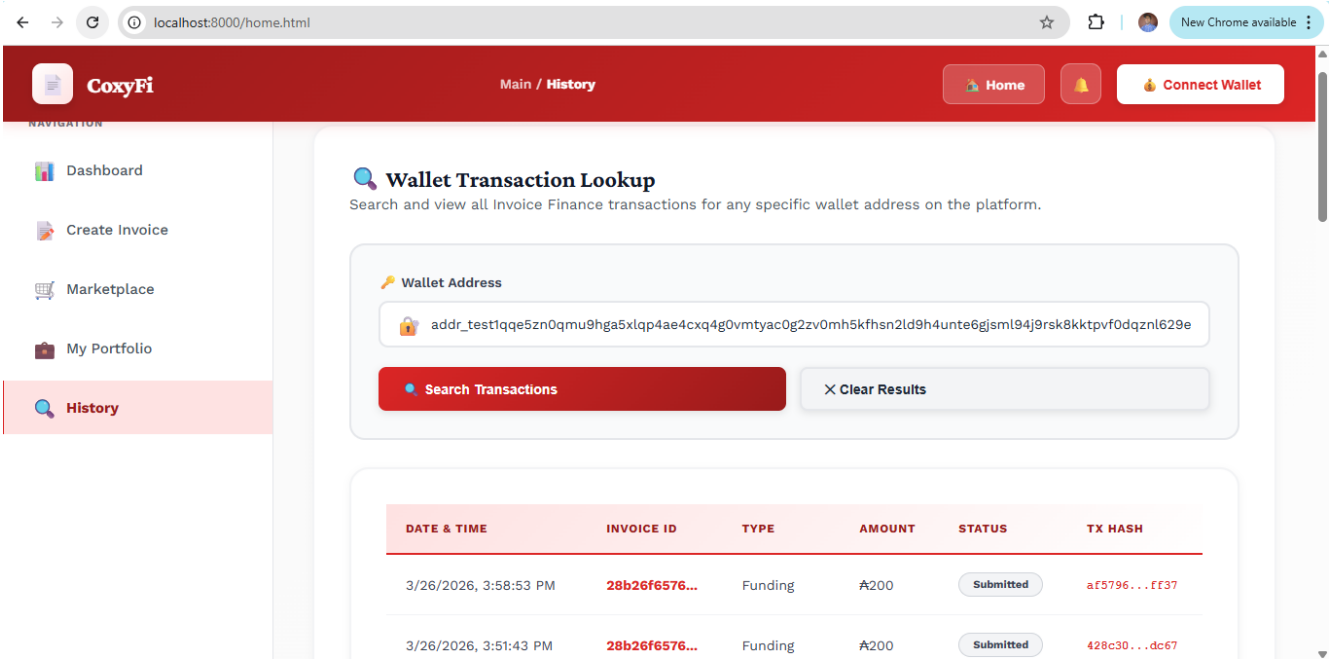


## 10. Transaction History, Search, and Export

Transaction tools provide operational transparency. Users should be able to inspect recent activity, search by wallet address, and export records.

- Recent transactions table with date, invoice id, action type, amount, status, and transaction hash
- Wallet-address search field and clear action
- Search results table with matching records
- CSV export action for recent activity

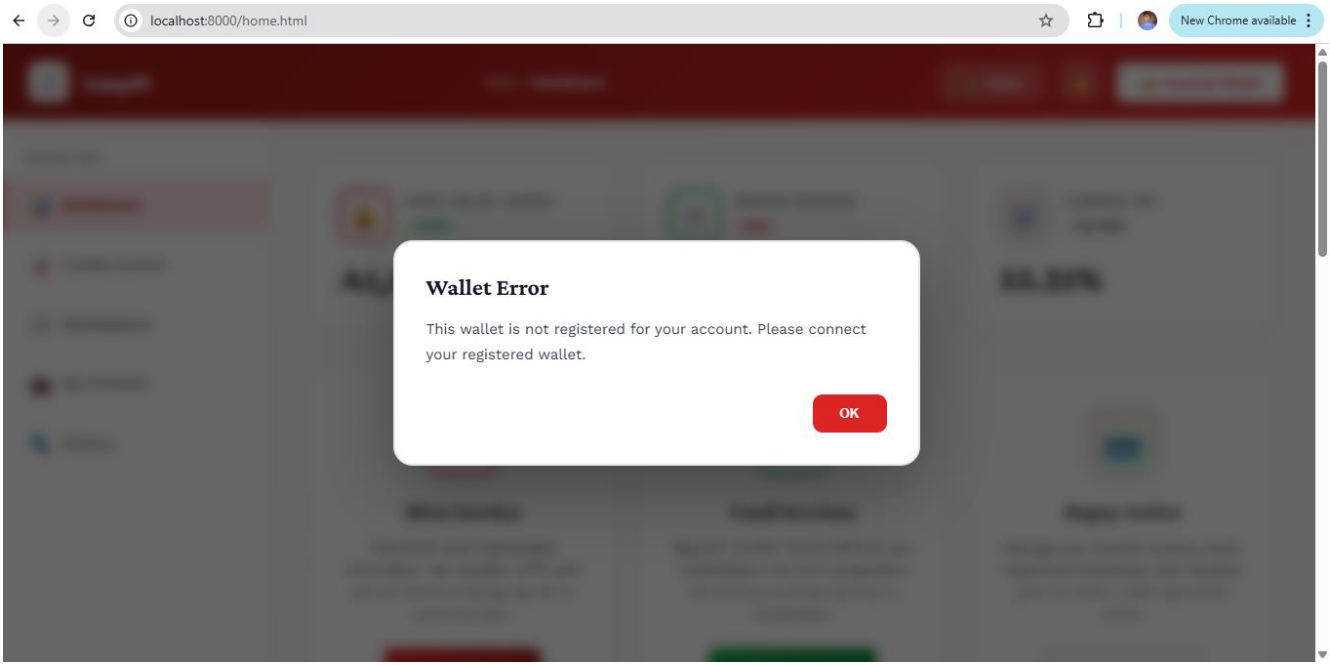




## 11. Security, Wallet Binding, and Status Feedback

Security-related design should be visible, not hidden. Users need constant reassurance that the app is using the correct wallet and that actions are safe to approve.

- Verified wallet binding confirmation
- Wrong wallet / blocked access modal
- Status log area for loading, success, warning, and failure messages
- Clear connection state in the header



## 12. Reusable UI Components

To keep the design system consistent, the following components should be reusable across pages:

- Primary and secondary buttons
- Card containers
- Status badges
- File upload input pattern
- Form text inputs and number inputs
- Modal dialog pattern
- Data tables
- Empty-state blocks
- Document preview image block

## 13. Responsive Behaviour

The front end should remain usable on smaller desktop widths and tablet-class screens, even if the primary experience is desktop-first.

- Action cards should stack vertically when horizontal space reduces.
- Invoice grids should collapse from multiple columns into one or two columns depending on width.
- Tables should preserve readability through horizontal scroll wrappers if necessary.
- Buttons should remain easy to tap and not collapse into unreadable widths.

## 14. Accessibility and Usability Notes

- Use clear labels for all inputs; do not rely only on placeholders.
- Maintain strong contrast for red, green, and white brand colors.
- Provide descriptive button text rather than vague labels.
- Ensure status messages are readable and persist long enough for users to notice them.
- Keep keyboard focus visible for forms, buttons, and links.

## 15. Future Front-End Enhancements

The current design can be extended in future iterations with:

- Dedicated invoice detail page with richer metadata
- Investor portfolio page
- Issuer profile and KYC status page
- Notifications center
- Advanced filtering and sorting in invoice marketplace
- Mobile-specific navigation pattern
- Integrated analytics and repayment forecasting

## 16. Summary

This front-end design document captures the main interaction surfaces required for the Invoice Finance DApp: onboarding, wallet connection, invoice creation, funding, repayment, and transaction review. The layout prioritizes clarity, trust, and operational efficiency.
